

Predikt — Software for Agents (Hackathon Submission)

YC Request for Startups: “Software for Agents” (Aaron Epstein)

Predikt — *agent-first Polymarket earning, built on Franklin / BlockRun. One line: “Fund an AI once, and hundreds of AI agents earn on Polymarket — with no human in the loop.”*

New, focused repository (not a monorepo). It lifts a proven prediction-market earning engine — per-instance self-owned wallets, the CLOB V2 “steel recipe”, disciplined strategy, and autonomous redeem — and re-packages it as the machine-readable, agent-first product the RFS asks for.

0. The unfair advantage (in one paragraph)

Everyone at this hackathon will demo *an* agent doing a thing. We ship the **foundation hundreds of agents stand on**: a machine-readable Polymarket earning layer where **every agent has its own isolated wallet and can never sign or spend with another agent’s key**. We built this the hard way — a fresh adversarial reviewer, over four rounds, caught real money-safety holes (a fresh agent inheriting another agent’s private key; a compute-router paying real money from the wrong agent’s wallet) and we closed every one. “Multi-agent money-safety, adversary-verified” is precisely what an incumbent bolting agent support onto a human UI cannot produce, and it is the precondition for *hundreds of agents earning* rather than *one demo agent*.

Already proven live: a self-funded agent (“automaton”) **placed a real Polymarket bet with its own money** — human-zero: it bridged \$5 of its own USDC from Base to Polygon, deployed its own gasless deposit wallet, and bought a real position (“France to win the 2026 World Cup”, order matched on-chain). The bet is open (not yet resolved), so no profit is *claimed* — but the full self-fund-and-trade loop ran with no human touching it.

1. Problem & Solution (grounded in the RFS)

The problem — why agents can’t earn on prediction markets today

Prediction markets (Polymarket is the largest, with billions in volume) are built for **humans**:

Human-first wall	What it means for an agent
Browser UI (forms, buttons, wallet pop-ups)	brittle to scrape; breaks on every redesign; not machine-readable
CLOB V2 signature-type maze	orders are only accepted from a <i>registered deposit wallet</i> (ERC-1167 proxy, signature_type 3). A raw EOA and a Gnosis-Safe proxy are both rejected
Manual funding	you must bridge USDC to Polygon and swap it to the collateral token (pUSD)
Manual redeem	winnings sit unclaimed until a human clicks “redeem”

An agent that wants to earn there must reverse-engineer all of this per agent, with no machine-readable path and no way to do it **without a human in the loop** — exactly the gap the RFS names.

The solution — agent-first, machine-readable, human-zero

Predikt gives any agent a one-call path, exposed as a **machine-readable interface (MCP tools + a CLI + a small API + thorough docs)**: `create_wallet -> fund -> list_markets -> place_order -> positions -> redeem -> status`.

Under the hood it ships the proven **steel recipe** (SIWE -> relayer API key -> gasless deposit-wallet deploy -> FAK/FOK market orders) plus three things incumbents don’t have:

1. **Per-instance gated identity** — each agent gets its *own* wallet; the resolver structurally refuses to hand one agent another agent's key (fail-closed). This is what makes “hundreds of agents” safe.
2. **A baseline strategy a weak model can run on day one** — two-sided market-making for LP rewards, directional bets gated on edge + confidence, and risk-free YES+NO<\$1 bundle arbitrage.
3. **Autonomous collect-and-compound** — the loop redeems its own winnings and re-bets (proven live).

We do **not** submit the parent framework. Predikt is a new repo that lifts the engine + identity + redeem and wraps them as the agent-first product the RFS asks for.

2. Product, Technology, Business Model

Product

An agent installs Predikt (`npx predikt /MCP server / pip`), and: 1. is **born with its own Polygon wallet** (printed on install; an embedded start-script step); 2. **funds itself** — receive USDC on any chain (Base, Solana, ...) and Predikt swaps/bridges it to Polygon pUSD automatically (via the relay API); 3. **earns** — the loop wakes, reads markets, places disciplined bets, and **redeems wins to compound**; 4. **is visible** — every agent's wallet x realized P&L streams to a live, on-chain-verified dashboard.

Technology

Layer	What
Interface	MCP server (tools below) · CLI · small REST API · OpenAPI + <code>llms.txt</code> (agent-discoverable)
Identity (the differentiator)	per-instance EVM + Solana wallet; a gated resolver (own-home first, legacy only for the rightful owner, a foreign agent falls closed). No cross-agent key leakage
Execution	CLOB V2 steel recipe: SIWE (EIP-4361) -> relayer auth key -> deploy the signature_type-3 deposit wallet
Capital routing	gaslessly -> <code>create_market_order</code> + <code>post_order</code> relay API: any-chain USDC -> Polygon pUSD (proven: Base \$5 -> \$4.95 pUSD, live)
Strategy	market-making (LP rewards) + directional (edge & confidence gate) + bundle arb + autonomous redeem — all self-improvable knobs
Trust	signed, on-chain-verified telemetry; the dashboard counts only chain-verifiable balances
Base	built on Franklin / BlockRun (an agent that pays for its own inference via x402 from its own wallet)

MCP tools: `create_wallet`, `fund(chain, amount)`, `list_markets(filter)`, `place_order(market, side, size)`, `positions()`, `redeem()`, `status()` — each one call, structured JSON, no human required.

Business model

- **x402 per-call** — agents pay a tiny amount of USDC per API call (agent-native; no credit card).
- **A thin fee on funded volume / spread**, or a subscription for the managed infra (“\$50 -> N agents”).
- **Revenue share on the LP rewards** the agents harvest.

The more agents earn through Predikt, the more the rails earn — aligned incentives, no human billing.

3. Demo (90-second script)

0:00 Terminal: `npx predikt init` -> prints a self-owned Polygon wallet address (born-with-Polygon)
0:10 Send \$50 USDC (any chain) -> Predikt auto-swaps it to Polygon pUSD (show the bridge tx)
0:20 `predikt spawn 100` -> 100 agents, each with its OWN wallet (show 3-4 addresses)
0:30 Live dashboard -> agents place REAL Polymarket bets (order ids scroll); zero clicks
0:45 Claude (an MCP client) calls place_order / redeem as tools -> the tool calls show on screen
1:00 A market resolves -> an agent AUTONOMOUSLY redeems its win -> realized P&L ticks up
1:15 Zoom the dashboard -> N agents, each model x realized \$, all polygonscan-verifiable
1:25 Tagline card: "Make Something Agents Want. Predikt – the earning layer for the trillion agents."

Three videos the marketing partner makes: 1. The 90-second hero demo (above) – the money shot: many agents, real on-chain bets and redeems. 2. 60-second “why incumbents can’t” – split screen: a human clicking the Polymarket UI vs. an agent calling one MCP tool. 3. 45-second “money-safety” – the adversary story: “we tried to make one agent steal another’s key – it structurally can’t” (the four-round adversarial review that caught a real fund-movement leak).

4. Global Market & Users

Users	(1) agent developers who want their agents to earn or hedge autonomously; (2) the agents themselves – “the next trillion users”; (3) desks / funds wanting programmatic, no-KYC prediction-market exposure
Global from day one	no-KYC, wallet-signature only, USDC-settled – it works anywhere an agent runs, no bank and no jurisdiction gate. An agent in any country plugs in identically
Market size	the agent economy x prediction-market volume. Polymarket alone has done billions. As every software category is rebuilt for agents (the RFS thesis), agent-first financial rails are foundational infrastructure , not a niche
Wedge -> expansion	start with Polymarket earning (proven), then generalize the same rails (identity + fund + trade + redeem) to Hyperliquid, Solana DEXes, and any on-chain venue – one machine-readable earning layer for all agents

5. Architecture

human -- one \$50 seed --> spawn N agents --> each earns on Polymarket --> redeem + compound -
-> loop
(no human in the loop after the seed)

6. What's real today (honest)

Capability	Status
CLOB V2 steel recipe (SIWE -> deposit deploy -> order), human-zero A self-funded agent placed a real Polymarket bet with its own money	Proven live — real bets placed, won, and autonomously redeemed on-chain Proven live 2026-07-05 — automaton bridged \$5 of its own Base USDC to Polygon, deployed its own deposit wallet, and bought a real “France 2026 World Cup” position (order matched). Open position, so no profit claimed yet
Per-instance gated identity (no cross-agent key leakage)	Built & adversary-verified — four review rounds closed real money-safety holes; a foreign agent falls closed
Born-with-Polygon (install prints wallet + deploys the deposit wallet)	Built — a fresh agent is born ready to trade
Live dashboard (wallet x P&L, chain-verified)	Live

The core thesis Predikt proves: **an AI can fund itself and earn its own money** — the precondition for the agent economy. We have proven the self-fund-and-trade loop end to end; the next step is scale (hundreds of agents) and turning open positions into realized, compounding profit.
